Escaping Violence or Trapped by It? Long Run Effects of Civil Conflict on International Migration in Nepal

February 12, 2026

Abstract

1 Introduction

International migration of Nepalese people has been a common phenomenon even before nineteenth century when they used to travel to Lahore to join the army of the Sikh ruler Ranjit Singh which was further institutionalised with the recruitment of Nepalese to the British Gurkhas in 1815-16. Seddon et al. (2002) Foreign migration has been a by-product of stagnant rural economy

Voors et al. (2012) advocate that there are two pathways for an economy after civil war; if it destroys the social capital or increases impatience then it will reduce investment and growth, however if it triggers institutional improvements or alters preferences towards saving then income might even be higher than before.

2 Related Literature

Context of Civil Conflict

The roots of the conflict lay in long-standing political exclusion and regional inequality that democratic reforms in 1990 failed to address. Nepal's feudal legacy had concentrated land and political power among elites, leaving rural areas-particularly the mid-western hills-economically marginalized with limited access to education, healthcare and political representation.

Various literature have discussed on the direct and indirect effect of violence on migration. Indirect effect relate to economic dislocation or economic turmoil causing people to migrate from their usual

place of residence while the direct effect imply the threat of staying back rather than economic costs, push the households to move away. How does the violence impact migration- internal and external, differently is another issue.

3 Data

Bohra-Mishra and Massey (2011) The conflict intensity variable is defined on the basis of the month of war observed in a certain district. $months\,of\,war_d$ is defined as the total number of months, a district was exposed to conflict. This will be used as a baseline variable to represent the conflict intensity. This variable is constructed as below:

$$\text{conflict}_{d1} = \text{months of war}_d = \sum_{m=1}^{131} 1(\text{casualty}_{dm}). \tag{1}$$

$$1(\text{casualty}_{dm}) = \begin{cases} 1, & \text{if casualty}_{dm} > 0, \\ 0, & \text{otherwise.} \end{cases}$$

Subscripts d and m represent district and month of war. m takes the value upto 131 due to the fact that the Maoist conflict reigned from February 1996 to November 2006 with total of 131 months.

Table 1: Descriptive Statistics: Overall Sample (New Table)

Variable	N	Mean/%	SD	Min	Max

4 Empirical Strategy

We estimate:

$$y_{itdc} = \alpha + \beta_c \left(Conflict\,Exposure_d \times \lambda_c \right) + \lambda_c + \delta_t + \eta_d + X_i' + \varepsilon_{itdc}, \tag{2}$$

where y is an binary outcome variable for individual i going abroad or not in the year t, from district d and cohort c, $Conflict\,Exposure$ indicates the different measures for exposure to war, λ represents the cohort, λ_c denotes cohort fixed effect, δ_t is the year fixed effect and η_d represents district fixed effects. ε is a random, idiosyncratic error term. The coefficient β captures the average treatment effect on the treated. $X_i^{'}$ represents the individual level controls including the individual's sex, educational attainment and ethnicity.

Various measures of Conflict Exposure have been discussed in Equations 1 to
